**Key facts**

- Air pollution is a major environmental risk to health and is estimated to cause approximately 2 million premature deaths worldwide per year.
- Exposure to air pollutants is largely beyond the control of individuals and requires action by public authorities at the national, regional and even international levels.
- The *WHO Air quality guidelines* represent the most widely agreed and up-to-date assessment of health effects of air pollution, recommending targets for air quality at which the health risks are significantly reduced.
- By reducing particulate matter (PM$_{10}$) pollution from 70 to 20 micrograms per cubic metre, we can cut air quality related deaths by around 15%.
- By reducing air pollution levels, we can help countries reduce the global burden of disease from respiratory infections, heart disease, and lung cancer.
- The WHO guidelines provide interim targets for countries that still have very high levels of air pollution to encourage the gradual cutting down of emissions. These interim targets are: a maximum of three days a year with up to 150 micrograms of PM$_{10}$ per cubic metre (for short term peaks of air pollution), and 70 micrograms per cubic metre for long term exposures to PM$_{10}$.
- More than half of the burden from air pollution on human health is borne by people in developing countries. In many cities, the average annual levels of PM$_{10}$ (the main source of which is the burning of fossil fuels) exceed 70 micrograms per cubic metre. The guidelines say that, to prevent ill health, those levels should be lower than 20 micrograms per cubic metre.

**Background**

Air pollution, both indoors and outdoors, is a major environmental health problem affecting everyone in developed and developing countries alike. The 2005 *WHO Air quality guidelines* (AQGs) are designed to offer global guidance on reducing the health impacts of air pollution. The guidelines
first produced in 1987\(^1\) and updated in 1997\(^2\) had a European scope. The new (2005) guidelines apply worldwide and are based on expert evaluation of current scientific evidence. They recommend revised limits for the concentration of selected air pollutants: particulate matter (PM), ozone (O3), nitrogen dioxide (NO2) and sulfur dioxide (SO2), applicable across all WHO regions.

Key findings in 2005 Air Quality Guidelines:

- There are serious risks to health from exposure to PM and O3 in many cities of developed and developing countries. It is possible to derive a quantitative relationship between the pollution levels and specific health outcomes (increased mortality or morbidity). This allows invaluable insights into the health improvements that could be expected if air pollution is reduced.
- Even relatively low concentrations of air pollutants have been related to a range of adverse health effects.
- Poor indoor air quality may pose a risk to the health of over half of the world’s population. In homes where biomass fuels and coal are used for cooking and heating, PM levels may be 10–50 times higher than the guideline values.
- Significant reduction of exposure to air pollution can be achieved through lowering the concentrations of several of the most common air pollutants emitted during the combustion of fossil fuels. Such measures will also reduce greenhouse gases and contribute to the mitigation of global warming.

In addition to guideline values, the AQGs give interim targets related to outdoor air pollution, for each air pollutant, aimed at promoting a gradual shift from high to lower concentrations. If these targets were to be achieved, significant reductions in risks for acute and chronic health effects from air pollution can be expected. Progress towards the guideline values, however, should be the ultimate objective.

**Particulate matter**

Guideline values

PM\(_{2.5}\)

10 \(\mu g/m^3\) annual mean
25 \(\mu g/m^3\) 24-hour mean

PM\(_{10}\)

20 \(\mu g/m^3\) annual mean
50 \(\mu g/m^3\) 24-hour mean

The 2005 AQG set for the first time a guideline value for particulate matter (PM). The aim is to achieve the lowest concentrations possible. As no threshold for PM has been identified below which no damage to health is observed, the recommended value should represent an acceptable and achievable objective to minimize health effects in the context of local
constraints, capabilities and public health priorities.

**Definition and principle sources**
PM affects more people than any other pollutant. The major components of PM are sulfate, nitrates, ammonia, sodium chloride, carbon, mineral dust and water. It consists of a complex mixture of solid and liquid particles of organic and inorganic substances suspended in the air. The particles are identified according to their aerodynamic diameter, as either PM\(_{10}\) (particles with an aerodynamic diameter smaller than 10 µm) or PM\(_{2.5}\) (aerodynamic diameter smaller than 2.5 µm). The latter are more dangerous since, when inhaled, they may reach the peripheral regions of the bronchioles, and interfere with gas exchange inside the lungs.

**Health effects**
The effects of PM on health occur at levels of exposure currently being experienced by most urban and rural populations in both developed and developing countries. Chronic exposure to particles contributes to the risk of developing cardiovascular and respiratory diseases, as well as of lung cancer. In developing countries, exposure to pollutants from indoor combustion of solid fuels on open fires or traditional stoves increases the risk of acute lower respiratory infections and associated mortality among young children; indoor air pollution from solid fuel use is also a major risk factor for chronic obstructive pulmonary disease and lung cancer among adults. The mortality in cities with high levels of pollution exceeds that observed in relatively cleaner cities by 15–20%. Even in the EU, average life expectancy is 8.6 months lower due to exposure to PM\(_{2.5}\) produced by human activities.

**Ozone (O\(_3\))**

**Guideline values**

\[ \text{O}_3 \]

100 µg/m\(^3\) 8-hour mean

The previously recommended limit, which was fixed at 120 µg/m\(^3\) 8-hour mean, has been reduced to 100 µg/m\(^3\) based on recent conclusive associations between daily mortality and ozone levels occurring at ozone concentrations below 120 µg/m\(^3\).

**Definition and principal sources**
Ozone at ground level – not to be confused with the ozone layer in the upper atmosphere – is one of the major constituents of photochemical smog. It is formed by the reaction with sunlight (photochemical reaction) of pollutants such as nitrogen oxides (NO\(_x\)) from vehicle and industry emissions and volatile organic compounds (VOCs) emitted by vehicles, solvents and industry. The highest levels of ozone pollution occur during periods of sunny weather.
Health effects
Excessive ozone in the air can have a marked effect on human health. It can cause breathing problems, trigger asthma, reduce lung function and cause lung diseases. In Europe it is currently one of the air pollutants of most concern. Several European studies have reported that the daily mortality rises by 0.3% and that for heart diseases by 0.4 %, per 10 µg/m³ increase in ozone exposure.

Nitrogen dioxide (NO₂)

Guideline values

NO₂
40 µg/m³ annual mean
200 µg/m³ 1-hour mean

The current WHO guideline value of 40 µg/m³ (annual mean) set to protect the public from the health effects of gaseous NO₂ remains unchanged from the level recommended in the previous AQGs.

Definition and principle sources

As an air pollutant, NO₂ has several correlated activities:

- At short-term concentrations exceeding 200 µg/m³, it is a toxic gas which causes significant inflammation of the airways.
- NO₂ is the main source of nitrate aerosols, which form an important fraction of PM₂.₅ and, in the presence of ultraviolet light, of ozone.

The major sources of anthropogenic emissions of NO₂ are combustion processes (heating, power generation, and engines in vehicles and ships).

Health effects

Epidemiological studies have shown that symptoms of bronchitis in asthmatic children increase in association with long-term exposure to NO₂. Reduced lung function growth is also linked to NO₂ at concentrations currently measured (or observed) in cities of Europe and North America.

Sulfur dioxide (SO₂)

Guideline values

SO₂
20 µg/m³ 24-hour mean
500 µg/m³ 10-minute mean

A SO₂ concentration of 500 µg/m³ should not be exceeded over average periods of 10 minutes duration. Studies indicate that a proportion of people with asthma experience changes in pulmonary function and
respiratory symptoms after periods of exposure to SO\textsubscript{2} as short as 10 minutes.

The revision of the 24-hour guideline for SO\textsubscript{2} from 125 to 20 μg/m\textsuperscript{3} is based on the following considerations:

- Health effects are now known to be associated with much lower levels of SO\textsubscript{2} than previously believed.
- A greater degree of protection is needed.
- Although the causality of the effects of low concentrations of SO\textsubscript{2} is still uncertain, reducing SO\textsubscript{2} concentrations is likely to decrease exposure to co-pollutants.

**Definition and principal sources**

SO\textsubscript{2} is a colourless gas with a sharp odour. It is produced from the burning of fossil fuels (coal and oil) and the smelting of mineral ores that contain sulfur. The main anthropogenic source of SO\textsubscript{2} is the burning of sulfur-containing fossil fuels for domestic heating, power generation and motor vehicles.

**Health effects**

SO\textsubscript{2} can affect the respiratory system and the functions of the lungs, and causes irritation of the eyes. Inflammation of the respiratory tract causes coughing, mucus secretion, aggravation of asthma and chronic bronchitis and makes people more prone to infections of the respiratory tract. Hospital admissions for cardiac disease and mortality increase on days with higher SO\textsubscript{2} levels. When SO\textsubscript{2} combines with water, it forms sulfuric acid; this is the main component of acid rain which is a cause of deforestation.

WHO will assist the Member States in sharing information on successful approaches, on methods of exposure assessment and monitoring of health impacts of pollution.
